**THE GEOLOGY AND GENESIS
OF IRON OXIDE-COPPER-GOLD
MINERALISATION ASSOCIATED
WITH WERNECKE BRECCIA,
YUKON, CANADA**

VOLUME I

Thesis submitted by
Julie Hunt B.Sc., M.Sc., PGeo.

in April 2005
for the degree of Doctor of Philosophy
in the School of Earth Sciences,
James Cook University, Queensland, Australia

“It is precisely for this that I love geology. It is infinite and ill defined: like poetry, it immerses itself in mysteries and floats among them without drowning. It does not manage to lay bare the unknown, but it flaps the surrounding veils to and fro; and every so often gleams of light escape and dazzle one’s vision.”

R. Topfler

Frontispiece: Bonnet Plume River valley, Wernecke Mountains, Yukon, Canada

STATEMENT OF ACCESS

I, the undersigned, author of this work, understand that James Cook University will make this thesis available for use within the University Library and, via the Australian Digital Theses network, for use elsewhere.

I understand that, as an unpublished work, a thesis has significant protection under the Copyright Act and;

I do not wish to place any further restriction on access to this work, with the exception of the following:

All users consulting this thesis are required to sign the following statement:

“In consulting this thesis I agree not to copy or closely paraphrase it in whole or in part without the written consent of the author, and to make proper written acknowledgement for any assistance which I have obtained from it.”

Julie Hunt

STATEMENT OF SOURCES

DECLARATION

I declare that this thesis is my own work and has not been submitted in any other form for another degree or diploma at any university or other institution of tertiary education. Information derived from the published or unpublished work of others has been acknowledged in the text and a list of references is given.

Julie Hunt

2005

ABSTRACT

The large scale Wernecke Breccia system occurs throughout the 13 km-thick Early Proterozoic Wernecke Supergroup (WSG) and is spatially associated with regional-scale faults. Breccia emplacement made use of pre-existing crustal weaknesses and permeable zones; metaevaporitic rocks in the lower WSG may be intimately related to breccia formation. The breccia bodies host vein and disseminated iron oxide-copper-gold \pm uranium \pm cobalt mineralisation and are associated with extensive sodic and/or potassic metasomatic alteration overprinted by pervasive carbonate alteration. Multiple phases of brecciation, alteration and mineralisation are evident. Six widely spaced breccia bodies that occur in different part of the WSG were examined in this study (i.e. Slab, Hoover, Slats-Frosty, Slats-Wallbanger, Igor and Olympic). New information includes geological, paragenetic, geochronological, isotopic, fluid inclusion thermometric and compositional data.

Re-Os analyses of molybdenite from a late-stage vein that cross-cuts breccia gave model ages of 1601 ± 6 and 1609 ± 6 Ma. These ages range from older than to within error of the *ca.* 1594.8 ± 4.6 Ma published U-Pb (titanite) date for breccia in the same area. A second molybdenite sample from a late-stage vein gave a Re-Os model age of 1648 ± 5.97 Ma. This date is considered analytically sound but the significance of it is not clear as it is believed to cut the *ca.* 1595 Ma breccia. Step heating ^{40}Ar - ^{39}Ar analyses carried out on muscovite from Wernecke Breccia matrix, a syn-breccia vein and two late-stage veins yielded dates of 1178.0 ± 6.1 , 1135.0 ± 5.5 , 1052 ± 10 and 996.7 ± 8 Ma respectively. These dates are significantly younger than the minimum age (*ca.* 1380 Ma) of Wernecke Breccia indicated by cross-cutting relationships and must have been reset. Samples submitted for U-Pb and Pb-Pb analyses gave discordant results that cannot be used to constrain the age of Wernecke Breccia or Wernecke Supergroup.

Fluids that formed Wernecke Breccia were hot (185-350 °C), saline (24-42 wt. % NaCl eq.) NaCl-CaCl₂ brines. Isotopic compositions for hydrothermal minerals range from: $\delta^{13}\text{C}_{\text{carbonate}} \approx -7$ to $+1$ ‰ (PDB), $\delta^{18}\text{O}_{\text{carbonate}} \approx -2$ and 20 ‰ (SMOW), $\delta^{34}\text{S}_{\text{pyrite/chalcopyrite}} \approx -13$ to $+14$ ‰ (CDT) and $\delta^{34}\text{S}_{\text{barite}} \approx 7$ to 18 ‰. Calculated $\delta^{18}\text{O}_{\text{fluid}} \approx -8$ to $+14$ ‰. The isotopic compositions indicate fluids were likely derived from formation/metamorphic water mixed with variable amounts of organic water \pm evolved

meteoric and/or evolved seawater. Metals and sulphur were probably derived from host strata and fluids circulated via tectonic (and/or gravity) processes. Magmatic waters are considered less likely as a fluid source because the isotopic data do not have a magmatic signature and mafic to igneous rocks spatially associated with the breccia are significantly older (i.e. *ca.* 1710 vs. 1600 Ma) thus ruling out a genetic connection. This suggests IOCG mineralisation can occur in non-magmatic environments and a division of the broad IOCG class into magmatic and non-magmatic end-members, with hybrid types in between, is suggested that reflects the involvement of magmatic and non-magmatic fluids. Wernecke Breccia and Redbank are representative of non-magmatic end-members, Lightning Creek is a magmatic end-member and hybrid types include Ernest Henry and Olympic Dam.

ACKNOWLEDGEMENTS

Funding for this project was provided in part by the Yukon Geology Program. Additional funding was provided by an Australian International Postgraduate Research Scholarship, a James Cook University scholarship and Merit Research Grant, a Society of Economic Geologists Student Research Grant, and a predictive mineral discovery* Cooperative Research Centre scholarship. Newmont Mines Ltd. and Archer, Cathro and Associates (1981) Inc. kindly allowed us access to their Wernecke Breccia properties and diamond drill core. Tom Setterfield of Monster Copper Resources Ltd gave an informative tour of the Monster Cu property. Al Doherty, on behalf of Blackstone Resources Ltd, gave a tour of the Hem claims. Thanks are due to Dave Caulfield, Henry Awmak and Mark Baknes of Equity Engineering Ltd and Mike Stammers of Pamicon Developments Limited for access to data at the beginning of the project that got the whole process underway. Melanie Brookes and David Gillen braved Yukon summers to provide assistance in the field. Curtis Freeman and Joel Clarkson of TransNorth Helicopters provided exceptional service.

Huge thanks are due to Grant Abbott and the Yukon Geological Survey for support throughout this project and to Tim Baker for his never failing support and encouragement. This project has also benefited greatly from collaboration and discussion with many people, including Derek Thorkelson, Gary Davidson, James Cleverly, Geordie Mark, Robert Creaser, Dave Selby, Mike Villeneuve, Tony Fallick, Chris Clarkson, Martin Hand and Roland Maas and they are thanked for their participation. Thanks to all at JCU who helped and encouraged me throughout this project especially Lucy, James, Kylie, Karen, Damien and Nicole and finally, thanks to Grant for his help and support in the Yukon and Australia.

TABLE OF CONTENTS - VOLUME II

LIST OF FIGURES

SECTION A

1. Location of study area, distribution of WSG and Wernecke Breccia plus location of breccia-associated IOCG prospects included in this study (modified from Thorkelson, 2000).
2. Simplified geology map of the study area (for details see Thorkelson, 2000 and Thorkelson *et al.*, 2002). Legend shows approximate stratigraphic position of IOCG prospects included in this study.
3. Time stratigraphic column of the study area showing major depositional, intrusive and deformational events (modified from Thorkelson, 2000).
4. WSG a) stratigraphic column, see text and Table 1 for unit descriptions (information from Delaney, 1981), b) typical FLG, c) probable meta-evaporite in F-Tr, d) typical Quartet Group and e) GLG stromatolitic dolostone.
5. View of Slab mountain and Slab ridge (looking south) showing location of metaevaporites. Insets: detail of metaevaporites in outcrop showing one thick (labelled) and several narrow (light coloured) scapolite-rich layers and detail of solution breccia that overlies metaevaporites.
6. Examples of Wernecke Breccia: a) clast supported breccia, Slab area, b) matrix supported breccia, Olympic area, c) breccia with abundant clasts of earlier breccia, Slab area, d) photomicrograph of Wernecke Breccia matrix (crossed polars) made up dominantly of sedimentary rock fragments, carbonate, feldspar, lesser quartz and minor hematite and magnetite, e) sharp contact between breccia and phyllitic metasiltstone, Hoover area, f) crackle brecciated metasiltstone from a gradational breccia contact, Hoover area.
7. Slab mountain area showing location of 'Slab mountain', 'Slab ridge', 'Slab creek', Bonnet Plume River, fold axial trace in the river valley, Wernecke Breccia, high strain zone, breccia that contains deformed clasts of phyllite and large clast of Slab volcanics with some of the flows outlined.
8. Hoover area showing location of FLG, Quartet Group, marker carbonate horizon and upper and lower breccias. (Photo taken by DJ Thorkelson).

9. Igor area showing location of 'Igor ridge', fold axial trace in 'Igor creek', Wernecke Breccia, Quartet Group and Cambrian strata.
10. Examples of alteration and mineralization: a) grey sodic-altered breccia, b) red potassic-altered breccia, c) biotite-scapolite alteration in FLG metasilstone cut by albite veins, cross-cut by calcite vein, d) potassic-altered Quartet Group metasilstone cut by dolomite-chalcopyrite vein, e) ankerite-magnetite vein cutting FLG, Slab prospect, f) massive chalcopyrite-pyrite vein cutting FLG, Slab prospect, g) clast of massive sulphide in breccia, Slab prospect, h) calcite-chalcopyrite vein cutting FLG, Slab prospect and i) chalcopyrite forming matrix to breccia, Hoover prospect.
11. Composition of a) feldspar and b) carbonate in Wernecke samples, based on microprobe data. Analyses were obtained with the James Cook University electron microprobe in wavelength dispersive mode, at an accelerating voltage of 15 kV and a current of 20 nA.
12. Examples of mineralization and deformation: a) massive magnetite-coarsely crystalline hematite-ankerite-quartz vein, Slats-Frosty area, b) euhedral magnetite replaced by hematite (rl), Igor prospect, c) euhedral magnetite overgrown by pyrite (rl), Igor prospect, d) hematite overgrown by pyrite with chalcopyrite filling fractures (rl), Olympic prospect, e) clasts of foliated metasilstone in Wernecke Breccia, f) foliated FLG cut by ankerite vein, both have been kinked during Racklan deformation and g) flattened clasts in foliated breccia. rl = reflected light.
13. Simplified paragenesis for prospects in the Wernecke Mountains: a) Slab, b) Hoover, c) Slats-Frosty, d) Slats-Wallbanger, e) Igor and f) Olympic prospects. NB: paragenetic stages apply only to a specific area, e.g. Slab stage 3 \neq Hoover stage 3 \neq Igor stage 3.
14. Cartoon depicting evolution of Wernecke Basin and structural controls on location of Wernecke Breccia. Stage I: deposition of FLG. Stage II: deposition of Quartet Group and GLG. Stage III: emplacement of Wernecke Breccia into pre-existing weak zones in deformed and metamorphosed WSG. Breccia bodies are widespread at the top of FLG in metaevaporite-bearing stratigraphy. See text for detailed description of stages.

SECTION B

1. Location of study area, distribution of WSG and Wernecke Breccia (modified from Thorkelson, 2000) plus simplified geology map of the study area (for details see Thorkelson, 2000 and Thorkelson *et al.*, 2002). Legend shows approximate stratigraphic position of IOCG prospects included in this study.
2. Time stratigraphic column of the Wernecke area showing major depositional, intrusive and deformational events (modified from Thorkelson, 2000).
3. Release spectra for ^{40}Ar - ^{39}Ar ages for muscovite from four Wernecke Breccia-related samples.
4. $^{207}\text{Pb}/^{235}\text{U}$ versus $^{206}\text{Pb}/^{238}\text{U}$ plot for three fractions of titanite from a Wernecke Breccia-related vein. Error for Pb/Pb age is quoted at the 2σ level.
5. $^{206}\text{Pb}/^{204}\text{Pb}$ versus $^{207}\text{Pb}/^{204}\text{Pb}$ plot for 5 analyses of a sample of GLG dolostone.

SECTION C

1. Location of study area, distribution of WSG and Wernecke Breccia plus location of breccia-associated IOCG prospects included in this study (modified from Thorkelson, 2000).
2. Simplified geology map of the study area (for details see Thorkelson, 2000 and Thorkelson *et al.*, 2002). Legend shows approximate stratigraphic position of IOCG prospects included in this study. Slats-F = Slats-Frosty, Slats-W = Slats Wallbanger.
3. Simplified paragenesis for prospects in the Wernecke Mountains: a) Slab, b) Hoover, c) Slats-Frosty, d) Slats-Wallbanger, e) Igor and f) Olympic prospects. NB: paragenetic stages apply only to a specific area, e.g. Slab stage 3 \neq Hoover stage 3 \neq Igor stage 3.
4. Photographs of fluid inclusion samples: Slab area - a) large crystals of quartz, calcite and fluorite locally make up the matrix of Wernecke Breccia, b) fluid inclusions in quartz crystal, c) fluid inclusions containing L + V + H and d) fluid inclusion containing L + V + H + h. L=liquid, V=vapour, H=halite, h=hematite; Hoover area - e) metasedimentary clast in Wernecke Breccia, f) trails of secondary fluid inclusions parallel to fractures within quartz in the clast; g) closer view of inclusions in f; Slats-Frosty area - h) ferroan dolomite-pyrite-fluorite vein cutting hematite-altered metasilstone; the fluorite contains pseudosecondary fluid inclusions, i) fluorite in h), note fluid inclusion trails parallel to fractures that do not

extend beyond the fluorite crystal, j) and k) liquid + vapour fluid inclusions in fluorite; Igor area – l) Wernecke Breccia sample with large barite and magnetite crystals, m) barite crystal in area shown in l); and Olympic area – n) Wernecke Breccia sample used for fluid inclusion analysis, o) quartz grain from breccia matrix with fluid inclusions in the outer rim, p) ferroan dolomite-quartz-chalcopyrite±pyrite vein and q) dolomite with primary fluid inclusions.

5. Summary of fluid inclusion data for samples from the Wernecke Mountains area. Th = final homogenisation temperature; NaCl eq wt % = equivalent weight % NaCl. See Table 1 caption for details of salinity calculations.
6. Comparison of fluid composition for inclusions from the Slab, Hoover, Slats-Frosty, Igor and Olympic areas using the NaCl-CaCl₂-H₂O system.
7. $\delta^{18}\text{O}$ versus $\delta^{13}\text{C}$ results for samples of hydrothermal carbonate from the Slab, Hoover, Slats-Frosty, Slats-Wallbanger, Igor and Olympic areas. Also shown are results for samples of host WSG limestone/dolostone from FLG, Quartet Group and GLG.
8. Overall $\delta^{18}\text{O}$ versus $\delta^{13}\text{C}$ results for carbonate samples from the Wernecke Mountains. Also shown are fields for common large earth reservoirs that are important in hydrothermal systems. Fields are from Taylor (1974), Sheppard (1977), Graham and Harman (1983), and Hoefs (1987) as compiled in Rollinson (1993). Mean values for Paleoproterozoic carbonates are from Shields and Veizer (2002). FLG = Fairchild Lake Group, Quartet Group = Quartet Group, GLG = Gillespie Lake Group.
9. $\delta^{34}\text{S}$ results for samples from the Slab, Hoover, Slats-Frosty, Slats-Wallbanger, Igor and Olympic areas. See text for discussion.
10. Overall $\delta^{34}\text{S}$ results for samples from the Wernecke Mountains. Also shown are fields for common large earth reservoirs that are important in hydrothermal systems. Fields are from Chambers (1982), Kerridge *et al.* (1983) and Chaussidon *et al.* (1989) as compiled in Rollinson (1993).
11. Plot of calculated $\delta^{18}\text{O}_{\text{water}}$ versus δD_{water} values for mineral separates of biotite, muscovite and actinolite from Wernecke samples. See Appendix VII for sample descriptions. $\delta^{18}\text{O}_{\text{water}}$ values for biotite and muscovite were calculated using the fractionation equations of Zheng (1993). δD_{water} values for biotite and muscovite were calculated using the fractionation equations of Suzuoki and Epstein (1976).

$\delta^{18}\text{O}_{\text{water}}$ and δD_{water} values for actinolite were calculated using the fractionation equations of Zheng (1993) and Graham *et al.* (1984) respectively for Tremolite. Magmatic water and formation waters fields are from Taylor (1974). Meteoric water line is from Epstein *et al.* (1965) and Epstein (1970). The metamorphic waters field is from values in Taylor (1974) and Sheppard (1981) as compiled by Rollinson (1993). The fields for felsic magma and high temperature volcanic vapour are from Taylor (1992) and Giggenbach (1992) as shown in Hedenquist *et al.* (1998). Composition of ancient seawater from Sheppard (1986). Isotopic trends are given for: 1) seawater undergoing evaporation (Knauth and Beeunas, 1986), 2) meteoric waters undergoing exchange with ^{18}O in minerals, 3) evaporation of meteoric water and 4) isotopic compositions of Salton Sea and Lanzarote geothermal waters compared to their local meteoric waters (Sheppard, 1986). Black bars beneath the main figure are calculated $\delta^{18}\text{O}_{\text{water}}$ values for calcite, dolomite and siderite from the Slab, Hoover and Igor areas using the fractionation factors of Zheng (1999).

12. Examples of isochores from the Slab and Igor prospects. Diagrams were constructed using the programme Flinc-Calc that is based on the equations of Zhang and Fratz(1987) and Brown (1998).
13. Log $f\text{O}_2 - \log f\text{S}_2$ plot for Slab area fluids. The following equations were used to define the mineral stability fields. Log K values were calculated for temperature = 300 °C and pressure = 2500 bars using the programme “The Geochemists Workbench”® release 4.0.2 (GWB uses information from many sources, these are compiled for e.g. in Johnson *et al.*, 1992).

Reaction used	Equation	Log K
Pyrite-Magnetite:	$3 \text{FeS}_2 + 2 \text{O}_2(\text{g}) = \text{Fe}_3\text{O}_4 + 3 \text{S}_2(\text{g})$	-4.6
Pyrite-Hematite:	$4 \text{FeS}_2 + 3 \text{O}_2(\text{g}) = 2 \text{Fe}_2\text{O}_3 + 4 \text{S}_2(\text{g})$	33.88
Pyrrhotite-Magnetite:	$6 \text{FeS} + 4 \text{O}_2(\text{g}) = 2 \text{Fe}_3\text{O}_4 + 3 \text{S}_2$	55.34
Bornite-Chalcopyrite:	$\text{Cu}_3\text{FeS}_4 + 4 \text{FeS}_2 = 5 \text{CuFeS}_2 + \text{S}_2$	83.64
Graphite-CO2(g):	$\text{C} + \text{O}_2(\text{g}) = \text{CO}_2(\text{g})$	-6.93
Calcite-gypsum:	$2 \text{CaCO}_3 + \text{S}_2(\text{g}) + 3 \text{O}_2(\text{g}) + 4 \text{H}_2\text{O} = 2 \text{CaSO}_4 + 2 \text{CO}_2(\text{g})$	36.13

14. Plots of pH versus log $f\text{O}_2$ for the Slab area. a) using a medium value for log $a\text{H}_2\text{S}$ of -2.6, b) using a low value for log $a\text{H}_2\text{S}$ of -3.23 and c) using a high value for log $a\text{H}_2\text{S}$ of -1.97. The positions of δS^{34}_i contours are also shown in a); Numbers in boxes on contours are $\delta\text{S}^{34}_{\text{pyrite}}$ values calculated using $\delta\text{S}^{34}_{\Sigma\text{S}} = 0 \text{‰}$ (right side) and

$\delta S^{34}_{\Sigma S} = 18 \text{ ‰}$ (left side). The shaded oval shows approximate fluid conditions at Slab. The position of sulphur isotope contours were calculated using the method of Ohmoto (1972) and the following conditions: temperature = 300 °C, pressure = 2.5 kb, ionic strength = 3.2 (based on fluid inclusion data). Molality of species was calculated using the programme “The Geochemists Workbench”® release 4.0.2; the following species were most abundant.

Species	Molality	Mole Fraction
NaSO ₄ ⁻	0.6985	0.497
CaSO ₄ (aq)	0.3741	0.266
KSO ₄ ⁻	0.165	0.117
SO ₄ ⁻	0.1623	0.115
H ₂ S(aq)	2.51E-03	0.002
HSO ₄ ⁻	1.54E-03	0.001
HS ⁻	1.30E-03	0.001

SECTION D

1. Location of selected IOCG districts. Modified from Hitzman (2000).
2. Location of Wernecke belt, distribution of Wernecke Breccia and location of breccia-associated IOCG prospects included in this study (modified from Thorkelson, 2000) plus simplified bedrock geology map of the study area (for details see Thorkelson, 2000 and Thorkelson *et al.*, 2002, 2003). Legend shows approximate stratigraphic position of IOCG prospects studied.
3. Typical examples of Wernecke Breccia and associated IOCG mineralisation and alteration: **a)** grey sodic-altered breccia, **b)** red potassic-altered breccia, **c)** breccia with abundant clasts of earlier breccia, Slab area, **d)** photomicrograph of Wernecke Breccia matrix (crossed polars) made up dominantly of sedimentary rock fragments, carbonate, feldspar, lesser quartz and minor hematite and magnetite, **e)** calcite-chalcopyrite vein cutting FLG, Slab prospect, **f)** massive chalcopyrite-pyrite vein cutting FLG, Slab prospect, **g)** chalcopyrite forming matrix to breccia, Hoover prospect, **h)** massive magnetite-coarsely crystalline hematite-ankerite-quartz vein, Slats-Frosty area and **i)** photomicrograph of hematite overgrown by pyrite with chalcopyrite filling fractures (reflected light), Olympic prospect.
4. Fluid temperature and salinity for selected IOCG deposits and prospects. References and abbreviations as in Table 1.

5. Measured sulphur isotope compositions for mineralisation and calculated oxygen isotope compositions for mineralising fluid from selected IOCG deposits. Legend shows mineral(s) used for sulphur isotope analysis and mineral used to calculate oxygen isotopic composition of fluid. References and abbreviations as in Table 1. * Values calculated from actinolite are 5.4 if temperature of 200 °C is used or 9.5 if temperature of 450 °C is used (see text for details). For $\delta^{18}\text{O}$ values for magmatic, metamorphic, formation and meteoric waters and modern seawater – *cf.* Sheppard, 1986; Rollinson, 1993. For $\delta^{34}\text{S}$ values for mantle and evaporite sources –*cf.* Ohmoto and Goldhaber, 1997.
6. Suggested classification of IOCG systems into magmatic and non-magmatic end-members with hybrid IOCG systems in between. Placement in the classification indicates the degree of involvement of magmatic and/or non-magmatic fluids in the formation of the IOCG system. Placement is also affected by the environment of formation of the IOCG system, i.e., magmatic or non-magmatic, which is determined by whether or not there is a **temporal** association with igneous rocks. At the non-magmatic end of the IOCG spectrum it is possible for an IOCG system to have formed from non-magmatic fluids but to have a temporal relationship with a magmatic system, e.g. Salton Sea. See text for discussion and references.
7. Schematic model showing examples of hydrothermal alteration and mineralisation produced by the circulation of non-magmatic fluids (adapted from Barton and Johnson, 2000). Voluminous metal-depleted, sodic(-calcic) \pm shallow K feldspar-hematite alteration forms in inflow zones and along the fluid pathway(s) (*cf.* Barton and Johnson, 1996, 2000). Fluids are heated and as they rise and cool they produce intense sodic and/or potassic alteration (depends on host rock composition) plus overprinting and shallow hydrolytic alteration. Metals are leached along the flow path and precipitate due to cooling and/or fluid mixing.

LIST OF TABLES

SECTION A

1. Description of formations within WSG. Information from Delaney (1981).

2. Representative results of scapolite and biotite microprobe analyses. % meionite = $100 \text{ (Ca+Mg+Fe+Mn+Ti) / (Na+K+Ca+Mg+Fe+Mn+Ti)}$; marialite = 100 - meionite (after Deer *et al.*, 1992). Analyses were obtained with the James Cook University JEOL electron microprobe in wavelength dispersive mode, at an accelerating voltage of 15 kV and a current of 20 nA, ZAF corrections were used. ¹ average of 70 analyses, ² average of 10 analyses.
3. Main characteristics of IOCG prospects included in this study, see text for details. In mineralization column: V = vein, D = disseminated, B = forms breccia matrix.
¹Yukon MINFILE (2003) database number. Information from: ²(Thorkelson *et al.*, 2003), ³(Yukon MINFILE, 2003), ⁴(Stammers, 1995), ⁵(Eaton & Archer, 1981) and ⁶(Caulfield, 1994).

SECTION B

1. Summary of published age dates for Wernecke Breccia-related samples, WSG and Slab volcanics.
2. Summary of sample characteristics and new age dates obtained during this study.

SECTION C

1. Summary of fluid inclusion data for samples from the Wernecke Mountains area.
T_{fm} = temperature of first melting, T_{m_{ice}} = ice melting temperature, T_{m_{hh}} = hydrohalite melting temperature, T_{hv} = vapour homogenisation temperature, T_{hs} = halite dissolution temperature, T_h = final homogenisation temperature.
Temperatures in °C. NaCl eq wt % = equivalent weight % NaCl. NaCl eq wt % values for Slab were approximated using the graphical methods of Vanko *et al.* (1988) and Zwart & Touret (1994). Values for other areas were calculated from T_{m_{ice}}, T_{m_{hydrohalite}}, T_{h_{halite}} using the programme FlinCalc (J. Cleverley, written communication) which uses information from Zhang and Frantz (1987) and Brown (1998). In the paragenesis column P = primary, S = secondary and PS = pseudo secondary. In the FI (fluid inclusion) Type column L = liquid, V = vapour, H = halite and Op = opaque.
2. Summary of carbon and oxygen isotope results. * mean value for *ca.* 1.8 to 1.7 Ba carbonates is from Shields and Veizer (2002).

3. $\delta^{18}\text{O}_{\text{water}}$ values calculated from measured $\delta^{18}\text{O}$ values of syn-breccia carbonate samples.
4. Summary of sulphur isotope results
5. Summary of hydrogen and oxygen isotope results. Also shown are calculated δD and $\delta^{18}\text{O}$ values for co-existing water. #duplicate analysis. See figure 11 caption for calculation details.
6. Estimates of fluid temperature from fluid inclusion and stable isotope data. *All direct fluid inclusion analyses are minimum temperatures, i.e. not trapped during phase separation. ** Using fractionation factors of Sheppard and Schwarcz (1970) and Golyshev *et al.* (1981). *** Using fractionation factors of Ohmoto and Lasaga (1982).
7. Estimates of: 1) thickness of strata overlying the IOCG prospects based on stratigraphic measurements (Delaney, 1981); 2) depth of the prospects based on pressure estimates; 3) pressure from fluid inclusion data; and 4) trapping temperature of fluid (see text for discussion).

SECTION D

1. Size and grade of selected IOCG deposits. References: **Lightning Creek** – Perring *et al.*, 2000; Williams *et al.*, 1999; **Osborne** – Adshead, 1995; Perkins and Wyborn, 1996, 1998; Adshead *et al.*, 1998; Rubenach *et al.*, 2001; **Eloise** – Baker, 1998; Baker and Laing, 1998; Baker *et al.*, 2001; **Olympic Dam** – Roberts and Hudson, 1983, 1984; Creaser, 1989; Reeve *et al.*, 1990; Johnson and Cross, 1991; Oreskes and Einaudi, 1992; Oreskes and Hitzman, 1993; Eldridge and Danti, 1994; Haynes *et al.*, 1995; Reynolds, 2000; **Aitik** – Frietsch *et al.*, 1995, 1997; Carlon, 2000; Wanhainen *et al.*, 2003; **Candelaria** – Ullrich and Clark, 1999; Marschik and Fontboté, 1996, 2001; Marschik *et al.*, 2000; **Salobo** – Requia and Fontboté, 2000; Souza and Vieira, 2000; **Ernest Henry** – Twyerould, 1997; Ryan, 1998; Mark and Crookes, 1999; Mark *et al.*, 2000; Williams *et al.*, in progress; **Wernecke Breccia (Slab)** – Hunt *et al.*, 2004, 2005; **Tennant Creek (West Peko, Eldorado)** – Ahmad *et al.*, 1999; Skirrow and Walshe, 2002; **Redbank** – Orridge and Mason (1975); Knutson *et al.* (1979).
2. Fluid temperature, salinity, composition and source plus precipitation mechanisms for selected IOCG deposits. References and abbreviations as in Table 1.

3. Tectonic setting, main host rocks, confining structure(s) and age of mineralisation for selected IOCG deposits. References and abbreviations as in Table 1.
4. Regional and ore-related alteration types for selected IOCG deposits. References and abbreviations as in Table 1.

LIST OF APPENDICES

- I:** Results of microprobe analyses.
- II:** Analytical Protocols for Ar-Ar, U-Pb, Pb-Pb and Re-Os analyses
- III:** Thermometric data for fluid inclusions.
- IV:** Results of stable isotope analyses.
- V:** Calculations for $\log f_{O_2}$ versus $\log f_{S_2}$ plots.
- VI:** Calculations for pH versus $\log f_{O_2}$ plots.
- VII:** Rock sample locations and descriptions
